On the Bent Boolean Functions That are Symmetric

PETR SAVICKÝ

Bent functions are the boolean functions having the maximal possible Hamming distance from the linear boolean functions. Bent functions were introduced and first studied by O. S. Rothaus in 1976.

We prove that there are exactly four symmetric bent functions on every even number of variables. These functions are exactly the four symmetric quadratic polynomials of the given number of variables.

1. INTRODUCTION

It is well known (see [6]) that for every boolean function of n variables there exists a linear boolean function such that the Hamming distance of these two functions is at most $2^{n-1} - 2^{n/2-1}$. If n is even then there exist boolean functions such that the Hamming distance of any of them from every linear boolean function is at least $2^{n-1} - 2^{n/2-1}$. These functions are called bent in [6]. They are naturally defined in [6] through their discrete Fourier transform.

If n is odd, the $n-1$ variable bent function has the distance $2^{n-1} - 2^{(n-1)/2}$ from all linear boolean functions of n variables. The maximum possible distance of a boolean function from the set of all linear boolean functions is studied in coding theory as the covering radius of the first order Reed–Muller code. In this setting some further results are known for the case of odd number of variables; see, for example [3] and [5].

Every boolean function of n variables can be expressed as a polynomial over the two-element field in variables $x_1, x_2, \ldots, x_n$, which is of degree at most one in every variable. This polynomial is unique; see for instance [2, chapter 13, § 2]. We shall call the degree of the boolean function the degree of its corresponding polynomial.

The following results are proved in [6]. Every bent function of $n > 2$ variables has the degree at most $n/2$. For every even $n > 2$ there are bent functions of degree exactly $n/2$. These results can also be found in [2].

A boolean function is called symmetric if it does not depend on the order of variables. This means that it depends only on the number of unit values among the input variables. We prove that a symmetric boolean function of an even number of variables is bent iff it is quadratic. There are exactly four such functions for every even number of variables.

The symmetric bent functions and so-called semi-bent functions were used in [1] to separate two classes of circuits constructed from specific threshold gates. If desired, more information on boolean functions and their complexity can be found in [4] or [7].

2. PRELIMINARIES

We denote by B_n the set $\{0, 1\}^n$. We use the symbols x and t for the elements of B_n throughout this paper. We denote the number of unit values in $x \in B_n$ as $|x|$. Linear functions are the functions of the form $a_0 \oplus a_1 x_1 \oplus \cdots \oplus a_n x_n$, where $a_0, a_1, \ldots, a_n \in \{0, 1\}$ and $\oplus$ denotes the addition in the two-element field.

We use the Fourier transform of a boolean function in the same way as in [2].

0195-6698/94/040407 + 04 $08.00/0

DEFINITION 2.1. If $t, x \in B_n$ then let $\langle t, x\rangle = \bigoplus_{j=1}^{n} t_j x_j$.

DEFINITION 2.2. Let f be a boolean function. We define its Fourier transform as

$$\hat{F}(t) = \sum_{x \in B_n} (-1)^{f(x) \oplus \langle t, x\rangle}.$$

DEFINITION 2.3 ([6]). A boolean function of n variables is bent iff $|\hat{F}(t)| = 2^{n/2}$ for all t.

3. SYMMETRIC FUNCTIONS

A symmetric boolean function of n variables is any function expressible in the form $f(x) = c_{|x|}$, where $c_0, \ldots, c_n \in \{0, 1\}$. Let f be such a function. Directly from Definition 2.2, we obtain the following:

$$\hat{F}(t) = \sum_{k=0}^{n} (-1)^{c_k} \sum_{|x|=k} (-1)^{\langle t, x\rangle}. \tag{1}$$

Note that

$$\sum_{|x|=k} (-1)^{\langle t, x\rangle} = \sum_{j=0}^{k} (-1)^j \binom{|t|}{j} \binom{n-|t|}{k-j} = P_k(|t|, n),$$

where P_k is the Krawtchouk polynomial (see [2]). It may be easily verified that these polynomials have the following generating function:

$$(1-z)^{|t|}(1+z)^{n-|t|} = \sum_{k=0}^{n} P_k(|t|, n) z^k. \tag{2}$$

The main result is presented after two technical lemmas.

LEMMA 3.1. *Let f be a symmetric boolean function of n variables. If there exists $t \in B_n$ such that $|t| = n/2$ and $|\hat{F}(t)| = 2^{n/2}$, then $c_{2l+2} = c_{2l} \oplus 1$ holds for all $l = 0, \ldots, n/2 - 1$.*

PROOF. If $|t| = n/2$, then using (2) we obtain

$$\sum_{|x|=k} (-1)^{\langle t, x\rangle} = \begin{cases} 0 & \text{if } k \text{ odd}, \\ (-1)^l \binom{n/2}{l} & \text{if } k = 2l. \end{cases}$$

Therefore, the expression (1) for $\hat{F}(t)$ can be written as

$$\hat{F}(t) = \sum_{l=0}^{n/2} (-1)^{c_{2l}} (-1)^l \binom{n/2}{l}.$$

If c_{2l+2} is equal to c_{2l} for some $l \in \{0, \ldots, n/2 - 1\}$, then this sum contains non-zero members of opposite sign, and hence

$$|\hat{F}(t)| < \sum_{l=0}^{n/2} \binom{n/2}{l} = 2^{n/2}.$$

Since this contradicts our assumptions, we have $c_{2l+2} = c_{2l} \oplus 1$ for all $l = 0, \ldots, n/2 - 1$. □

LEMMA 3.2. *Let f be a symmetric boolean function of n variables. If there exists $t \in B_n$ such that $|t| = n/2 - 1$ and $|\hat{F}(t)| = 2^{n/2}$ and $c_{2l+2} = c_{2l} \oplus 1$ for all $l = 0, \ldots, n/2 - 1$, then $c_{2l+3} = c_{2l+1} \oplus 1$ holds for all $l = 0, \ldots, n/2 - 2$.*

PROOF. If $|t| = n/2 - 1$, then using (2) we obtain

$$\sum_{|x|=k} (-1)^{\langle t,x\rangle} = \begin{cases} (-1)^l \left[\binom{n/2-1}{l} - \binom{n/2-1}{l-1} \right], & k = 2l, \\ 2(-1)^l \binom{n/2-1}{l} & k = 2l+1. \end{cases}$$

Consequently, the terms for even k in (1) sum up to

$$\sum_{l=0}^{n/2} (-1)^{c_{2l}} (-1)^l \left[\binom{n/2-1}{l} - \binom{n/2-1}{l-1} \right].$$

Since $c_{2l+2} = c_{2l} \oplus 1$ by the assumptions of the lemma, $(-1)^{c_{2l}}(-1)^l = (-1)^{c_0}$ for all $l = 0, \ldots, n$, and hence the sum of even k terms in (1) is zero. It follows that

$$\hat{F}(t) = 2 \sum_{l=0}^{n/2-1} (-1)^{c_{2l+1}} (-1)^l \binom{n/2-1}{l}.$$

If c_{2l+1} is equal to c_{2l+3} for some $l \in \{0, \ldots, n/2 - 2\}$, then

$$|\hat{F}(t)| < 2 \sum_{l=0}^{n/2-1} \binom{n/2-1}{l} = 2^{n/2}.$$

This is a contradiction. Hence $c_{2l+3} = c_{2l+1} \oplus 1$ for all $l = 0, \ldots, n/2 - 2$. □

Now we can formulate the characterization of the symmetric bent functions.

THEOREM 3.3. *If $f(x) = c_{|x|}$ is a symmetric function of an even number n of variables, then the following statements are equivalent:*
(a) *the function f is a bent function;*
(b) *for all $k = 0, \ldots, n - 2$, the identity $c_{k+2} = c_k \oplus 1$ is satisfied;*
(c) *there exist constants $c, d \in \{0, 1\}$ such that, for all x,*

$$f(x) = \bigoplus_{i<j} x_i x_j \oplus \left(\bigoplus_i c x_i \right) \oplus d.$$

PROOF. (a) $\Rightarrow$ (b). This is a direct consequence of Lemmas 3.1 and 3.2.

(b) $\Rightarrow$ (a). In this step we use the complex numbers, and so we use i to denote the imaginary unit. Let us denote $\alpha = (-1)^{c_0} - \mathrm{i}(-1)^{c_1}$. If (b) is satisfied, then one can prove by induction that $(-1)^{c_k} = \mathrm{Re}(\alpha \mathrm{i}^k)$ for all $k = 0, \ldots, n - 2$. By substituting this into (1), we obtain that, for all $t \in B_n$,

$$\hat{F}(t) = \mathrm{Re}\left[\sum_{k=0}^{n} \alpha \mathrm{i}^k \sum_{|x|=k} (-1)^{\langle t,x\rangle} \right].$$

Using (2) with $z = \mathrm{i}$ we get:

$$\begin{aligned} \hat{F}(t) &= \mathrm{Re}[\alpha(1 - \mathrm{i})^{|t|}(1 + \mathrm{i})^{n-|t|}] = \mathrm{Re}[\alpha(1 + \mathrm{i})^n(-\mathrm{i})^{|t|}] \\ &= \mathrm{Re}[\alpha(2\mathrm{i})^{n/2}(-\mathrm{i})^{|t|}] = 2^{n/2} \mathrm{Re}[\alpha \mathrm{i}^{n/2}(-\mathrm{i})^{|t|}]. \end{aligned}$$

Since both the real and the imaginary parts of α are 1 or -1 and $n/2$ is a natural number, we obtain $|\hat{F}(t)| = 2^{n/2}$ for all $t \in B_n$, and hence f is a bent function.

(c) $\Leftrightarrow$ (b). Let $k \in \{0, \ldots, n\}$. It is easy to see that if (c) is satisfied and $|x| = k$ then

$$c_k = f(x) \equiv \binom{k}{2} + ck + d \bmod 2.$$

Since

$$\binom{k+2}{2} - \binom{k}{2} = 2k + 1$$

we obtain $c_{k+2} = c_k \oplus 1$ for $k = 0, \ldots, n-2$.

Let (b) be satisfied. If $c = c_1 \oplus c_0$ and $d = c_0$, then

$$c_k \equiv \binom{k}{2} + ck + d \bmod 2$$

is satisfied for $k = 0, 1$. Hence this identity is satisfied for all $k = 0, \ldots, n$, due to the fact that c_k and the parity of the right-hand side of this identity satisfy the same recurrence relation. Since $f(x) = c_{|x|}$, this implies (c). □
